

Project Idea Submission

Recently, while discussing placement preparation with my classmates, I noticed that many students were confused about their career readiness and lacked proper guidance regarding their technical strengths and weak areas. Most students prepare randomly without understanding whether their current skills are actually sufficient for placements or suitable for specific job roles. After observing this problem, I got the idea of building an AI-powered placement guidance system called “**PlacementMentorAI**”. The main purpose of this system is to help students analyze their technical profile and receive intelligent placement-related insights before attending interviews or campus recruitment drives. The idea is to collect important student information such as CGPA, programming skills, aptitude level, projects, certifications, communication ability, and technical interests. Using Machine Learning algorithms, the system will predict a student’s placement readiness score and determine whether the student is highly eligible, moderately eligible, or needs improvement for placements. In addition to prediction, the system will also provide personalized outputs such as suggested career roles, weak area identification, and recommended learning paths. For example, the system can suggest whether a student is more suitable for roles like ML Engineer, Backend Developer, Cloud Engineer, or Cybersecurity Analyst based on their skill profile. The long-term vision of this project is to create an intelligent AI-based career assistant that can guide students toward better placement preparation through data-driven analysis and personalized recommendations.
